

Model-implied welfare differences associated with regional job-access environments, holding observed individual characteristics fixed

NOT a causal region effect. The two profiles are the E1 forward pair's households, evaluated under every documented (NUTS-1 region x urbanisation) access environment with the local unemployment rate at that region's value for the person's own education and sex. Preferences, sex, age, education, potential experience, household composition, earning-capacity characteristics and the priced budget are held at their observed values; the region-dependent budget rule (the housing-allowance zone) belongs to endowments and needs and is held fixed too, so this is an ACCESS counterfactual and no price is recomputed. Because every geographic variable in the specification is employment-gated, the hours, occupation and wage-offer summaries do not move at all; the whole regional effect is on the employment margin.
