

The headline decomposition under two kinds of uncertainty, kept apart

The two intervals measure DIFFERENT things and are drawn on two offset rows so they cannot read as one. RQMC band: the accepted eight-scramble delete-one jackknife at a fixed theta-hat, $E_T = t(0.975, 7) \times se$ -- how well 2,048 nodes integrate the model, not sampling error. CR1 parameter interval: the 2.5th-97.5th percentile over $K = 100$ draws from $N(\theta\text{-hat}, CR1 \text{ covariance})$ at fixed nodes -- asymptotic parameter-draw simulation, NOT a bootstrap; nothing is resampled and nothing is re-estimated. 39 interior coordinates are drawn; 10 pinned and 2 free-but-at-a-bound coordinates are held at theta-hat, so every interval is CONDITIONAL ON THE ACTIVE SET observed there. The combined range is the union of the two and is not a confidence statement. Female-primary reference; final singles model; structural and model-conditional; not causal.
